  REN21
RENEWABLE ENERGY POLICY NETWORK FOR THE 21st CENTURY

REN21 is the only global renewable energy community of actors from science, governments, NGOs and industry. We provide up-to-date and peer-reviewed facts, figures and analysis of global developments in technology, policies and markets. Our goal: enable decision-makers to make the shift to renewable energy happen – now.

The most successful organisms, such as an octopus, have a decentralised intelligence and "sensing" function. This increases responsiveness to a changing environment. REN21 incarnates this approach.

Our more than 2,000 community members guide our co-operative work. They reflect the vast array of backgrounds and perspectives in society. As REN21's eyes and ears, they collect information and share intelligence, by sending input and feedback. REN21 takes all this information to better understand the current thinking around renewables and change norms. We also use this information to connect and grow the energy debate with non-energy players.

Our annual publications, the Renewables Global Status Report and the Renewables in Cities Global Status Report, are probably the world's most comprehensive crowdsourced reports on renewables. It is a truly collaborative process of co-authoring, data collection and peer reviewing.
This document presents the overarching renewable energy trends and perspectives from 2021 so that policy makers and other decision makers can more easily understand the significance of the latest developments. It outlines what is happening to drive the energy transition and details why it is not happening fast enough or as fast as possible. It draws on the meticulously documented data found in REN21’s Renewable 2021 Global Status Report. See the endnotes and methodological notes in the full report for further details, at www.ren21.net/gsr.
The year 2020 was one of new norms. As the world witnessed the tragic impacts of a pandemic, communities also experienced the health and well-being benefits stemming from the sudden decline in the use of fossil fuels, such as higher air quality and bluer skies. People also understood, collectively, the importance of governments mobilising quickly in the face of a crisis – in response not only to the immediate public health challenge and the economic recession that followed, but also to longer-term crises related to air pollution, climate change and biodiversity loss.

As a result, 2020 was also a year of accelerating ambition. The total number of national targets for achieving net zero emissions (including targets already in law, proposed and drafted) covered countries responsible for more than 80% of global carbon dioxide (CO₂) emissions. The public consensus increasingly reflects the emerging vision to move beyond fossil fuels, which are responsible for nearly 90% of CO₂ emissions. Under pressure from citizens, civil society and the courts, countries are being forced to strengthen their own climate plans, while fossil fuel companies are losing legal and shareholder battles. At the same time, businesses are buying ever larger amounts of renewable energy.

Renewable energy is central to the solution, both to continue to fight climate change at scale and to overcome the post-pandemic economic recession. Growing commitments towards net zero emissions highlight a rising tide of awareness of the urgent action needed to address climate change and air pollution and to accelerate sustainable development. Rising ambition and economic recovery packages also provide an opportunity to channel needed funding to renewable energy and further accelerate the transition.
However, a heightened profile does not automatically translate into action and implementation. Obstacles that have prevented the growth of renewable energy in past years continued during 2020. They include the lack of integrated, cross-sectoral strategies to drive the transition; the lack of sufficient policy support and enforcement; persistent support for fossil fuels; the need for infrastructure development and increased affordability in some markets; and the need for more innovation in some sectors. Together, they have led to only a slow increase in the share of renewable energy in final energy demand.

At the same time, the world is burning more fossil fuels than ever. Since 2009, the share of fossil fuels in final energy consumption has remained the same, and global energy demand has expanded around 20%. Renewable energy meets just over 11% of global final energy demand – only a slight increase from around 9% a decade ago.

Note: Totals may not add up due to rounding. This figure shows a comparison between two years across a 10-year span. The result of the economic recession in 2008 may have temporarily lowered the share of fossil fuels in total final energy consumption in 2009. The share in 2008 was 80.7%. Source: Based on IEA data.
The share of renewables has increased only moderately each year despite tremendous growth in some renewable energy sectors. Renewables grew almost 5% per year between 2009 and 2019, outpacing growth in fossil fuels (1.7%). However, energy demand also grew significantly over the period. As a result, renewables accounted for only one-quarter of the total growth in the world’s use of energy.

Energy efficiency also faced challenges in 2020. The rate of improvement in energy intensity (a common indicator of energy efficiency) has been declining since 2015, and in 2020 the rate was half that of the previous two years.

The persistent share of fossil fuels, as well as increasing energy demand, underscore the complementary and fundamental roles of energy conservation and efficiency alongside renewables to increase the renewable share while meeting global energy needs. However, energy conservation, energy efficiency and renewable energy are not enough by themselves; it is also necessary to leave fossil fuels in the ground and to phase out existing fossil fuel capacity.

Progress that has been made has occurred primarily in the power sector, where the share of renewables is highest. However, overall energy use in the power sector is much lower than energy consumed in other sectors, such as heating, cooling and transport. Together, these other sectors account for more than 80% of final energy demand, yet their renewable energy shares are much lower than for the power sector.

These sectors also saw more difficulty in 2020 than in past years. The uptake of modern renewables for heating and cooling progressed slowly, and consumption of renewable heat fell during the pandemic. Similarly, in contrast to previous years when the share of renewables showed some growth, albeit limited, the transport sector’s renewable energy share did not increase in 2020. The uptake of renewables in heating and transport is constrained by these sectors’ high dependence on fossil fuels, which is exacerbated by persistent fossil fuel subsidies, insufficient renewable energy policy support and enforcement, and slow developments in new technologies (such as advanced biofuels).

Source: Based on IEA data.
At the same time, **2020 offered some bright spots.** Although the early phase of the pandemic was a difficult period for renewables, new renewable power capacity hit a record increase globally. Renewables were the only source of electricity generation to experience a net increase. Investment in renewable power grew for the third consecutive year, and corporations continued to break records for sourcing renewable electricity. More countries are turning to electrification of heat with renewable energy, and although production of transport biofuels decreased, electric vehicle sales expanded, as did the linking of these vehicles to renewable electricity.

The status of renewable energy in 2020 shows that a **structural shift from fossil fuels to renewables is required.** A structural shift does not mean moderately increasing the share of renewable energy from one year to another. It does not mean gradually lowering the contribution of fossil fuels. It means transitioning from fossil fuels to a renewable energy-based system in all societal and economic activities. Targets, policies and investment are the tools on our workbench – and reaching significantly higher shares of renewable energy is the blueprint we must follow.
Renewable Energy Targets

Most of the world’s largest countries and greatest emitters of greenhouse gases lack clear, economy-wide objectives to shift to renewables in all sectors. Only five members of the G20 – the European Union (EU-27), France, Germany, Italy and the United Kingdom – had set 2020 targets to achieve a specific share of renewables in final energy use, and some were clearly not on track to achieve their own targets by year’s end.

Overall, 165 countries had targets in place to achieve certain levels of renewable energy by 2020. However, most of the targets were only for the power sector. In addition, these target-setters were not always on track leading up to 2021. Overall, some 80 targets for 2020 had already been met, while the majority (134) had not yet been achieved, according to the latest data available.

Even when countries meet their commitments, they do not always set new ones to chart the path towards higher ambition. Only half of the countries with 2020 targets had set later more ambitious targets by year’s end. Worse still, most of the countries that have not set new targets had not yet even achieved their first. In short, countries are missing the mark and are failing to plan ahead to increase their ambition.

**CALL TO ACTION**

Governments and businesses must set targets for renewable energy in all sectors and build on them with new, bolder goals by the time they meet the original target.
Countries do not achieve their targets in large part because they lack a supportive policy framework, or because the policy frameworks they have are ineffective or not enforced. This year of new norms – 2020 – highlighted inaction among the world’s policy makers and the lack of concrete measures to decarbonise their economies. It was the first year in which the number of countries with renewable energy support policies did not increase.

In addition, the heating and cooling and transport sectors lag far behind the power sector. While the number of countries with policies for renewable energy in transport plateaued in 2017, the number of countries with policies for heating and cooling peaked that year and has been declining ever since.

**Supportive policy frameworks are critical to build renewables-based energy systems around the world.** The successful uptake of renewable energy has been driven by bold policy making. However, unconditional support for propping up fossil fuels continues, while renewables receive far less support. The world will not reach its climate and development goals until renewable energy is prioritised.

In addition, stable policies are crucial to ensure that targets for renewables and net zero emissions are achieved. Today’s stop-and-go policy making poses a grave threat to the future development of renewables.

**CALL TO ACTION**

Targets have to be backed up by policies that support the uptake of renewables by incentivising and/or mandating their use. But this is not enough – governments also need to actively phase out the use of fossil fuels and fossil fuel subsidies.

**Number of Countries with Renewable Energy Regulatory Policies 2010–2020**

Note: Figure does not show all policy types in use. In many cases countries have enacted additional fiscal incentives or public finance mechanisms to support renewable energy. A country is considered to have a policy (and is counted a single time) when it has at least one national or state/provincial-level policy in place. Power policies include feed-in tariffs (FITs) / feed-in premiums, tendering, net metering and renewable portfolio standards. Heating and cooling policies include solar heat obligations, technology-neutral renewable heat obligations and renewable heat FITs. Transport policies include biodiesel obligations/mandates, ethanol obligations/mandates and non-blend mandates.
Global investment in renewable power capacity withstood the economic crisis triggered by the COVID-19 pandemic, totalling USD 303.5 billion in 2020. This 2% increase over 2019 marks a significant rebound, particularly given conditions at the start of the year.

However, this annual increase of 2% is well below necessary levels. At this rate, total growth in renewable energy investment will be only 22% by 2030. To reach global climate and sustainable development goals, annual investment in renewables must at least triple by 2030, for a total increase of 200%.

Economic recovery packages provide an opportunity to reorient investment. However, despite international calls to "build back better" during the COVID-19 crisis, investment in fossil fuels in COVID-19 recovery packages was six times higher than for renewable energy.

Beyond recovery funds, fossil fuel subsidies remain in the hundreds of billions of dollars, far above the support for renewables. In addition, investment in new fossil fuel production and related infrastructure continued in many countries. In 2020, the world saw the first annual increase in global coal capacity since 2015.

CALL TO ACTION

A structural shift means channelling funding from fossil fuels to energy conservation, energy efficiency and renewable energy. At the same time, the overall level of renewable energy investment must be increased dramatically.

Note: Although the energy produced from solid waste combustion is efficient, it cannot be considered entirely renewable as solid waste also contains inorganic material. Generally, about 50% of energy from municipal solid waste is classified as renewable. Multiple renewables include geothermal and ocean power. Enabling technologies include e-mobility and renewable hydrogen. The "Other" category refers to other types of energy-related policies including, among others, nuclear energy, incineration, hydrogen from unspecified sources, and multiple energy types (for example intertwined fossil fuels and clean energy). Where totals do not add up, the difference is due to rounding.

i See IEA, Net Zero by 2050 and IRENA, World Energy Transition Outlook (Preview).
Renewable Energy as a Key Performance Indicator in All Economic Activities

Nothing will happen unless we measure the right indicator. Considering the urgency of accelerating the structural shift from fossil fuels to renewables in all societal and economic activities, it is not enough anymore to track renewable energy targets, policies and investment. The world’s progress towards global climate and sustainable development goals can be measured by a simple key performance indicator: the share of renewable energy.

The share of renewable energy reflects developments in energy demand, energy conservation, energy efficiency and emissions in addition to renewable energy uptake and the reduction of fossil fuel use. Reaching a high renewable energy share can be used as the blueprint for a structural shift towards a transformed energy world.

Therefore, this indicator should be integrated at every level of decision making. Because energy is everywhere, the energy transition needs to happen everywhere. This particular key performance indicator lets people measure progress and ensure engagement globally, nationally, in regions, in cities, in any economic sector and even in businesses.

CALL TO ACTION

Make progress in renewables a key performance indicator in all economic activities, and use the renewable energy share to monitor advancement.

---

¹ Data are from BloombergNEF and include investment in new capacity of all biomass, geothermal and wind power projects of more than 1 MW; all hydropower projects of between 1 and 50 MW; all solar power projects, with those less than 1 MW estimated separately; all ocean power projects; and all biofuel projects with an annual production capacity of 1 million litres or more. Total investment values include estimates for undisclosed deals as well as company investment (venture capital, corporate and government research and development, private equity and public market new equity).

² The GSR strives to exclude pure pumped storage capacity from hydropower capacity data.

³ Solar PV data are provided in direct current (DC).

⁴ Includes bio-heat supplied by district energy networks and excludes the traditional use of biomass. See Reference Table R1 in the GSR 2021 Data Pack and related endnote for more information.

⁵ Includes glazed (flat-plate and vacuum tube) and unglazed collectors only. The number for 2020 is a preliminary estimate.

⁶ The estimate of annual growth in output is based on a survey report published in early 2020. The annual growth estimate for 2020 is based on the annualised growth rate in the five-year period since 2014.

⁷ A country is counted a single time if it has at least one national or state/provincial target or policy.

⁸ Biofuel policies include policies listed both under the biofuel obligation/mandate column in Table 6 and in Reference Table R8 in the GSR 2021 Data Pack.

⁹ Data reflect all countries where the policy has been used at any time up through the year of focus at the national or state/provincial level.

Note: All values are rounded to whole numbers except for numbers <15, biofuels and investment, which are rounded to one decimal point.

FAME = fatty acid methyl esters; HVO = hydrotreated vegetable oil.
What is the story?

The share of renewable energy in meeting heating and cooling needs is still low. It is increasing only slowly, despite large growth in some technologies, as shown below. In order to increase the use of renewable heating and cooling, policies are needed that improve the affordability of these technologies and level the playing field compared to fossil fuels.
**Sectoral Coverage of National Renewable Heating and Cooling Financial and Regulatory Policies**
as of End-2020

Number of sectors covered
- 4 sectors
- 3 sectors
- 2 sectors
- 1 sector
- Zero sectors or no data

Note: Sectors include residential, industrial, commercial and public facilities. Policy types used for map shading include investment subsidies/grants, rebates, tax credits, tax deductions, loans and feed-in tariffs. Renewable energy mandates are the obligation to meet a certain renewable standard for heat, such as the use of a specified technology. Other support policies include fossil fuel bans, support for phasing out fossil fuels, CO₂ pricing for heat and support for R&D. Figure does not show policies at the local level; for local level data, see REN21 Renewables in Cities Global Status Report, www.ren21.net/cities.

Overall, the transport sector is not on track to meet global climate targets for 2030 and 2050.

What is the story?

Transport is the sector with the lowest share of renewable energy. It is also a heavy energy-consuming sector, accounting for 32% of global final energy demand. Biofuels are the dominant source of renewable energy for transport, and the contribution of (renewable) electricity remains low. Policy attention is urgently needed to electrify transport with renewable energy and increase the use of renewable fuels.

National and Sub-National Renewable Transport Mandates
End-2020

Note: Shading shows countries and states/provinces with mandates for either biodiesel, ethanol or both.
Source: REN21 Policy Database.
**Avoid-Shift-Improve Framework in the Transport Sector**

**AVOID**
- Avoid or reduce the need for motorised travel
  - Transport demand management
  - Mixed-use, transit-oriented development
  - Active transport (e.g., walking, cycling)
  - Telecommuting

**SHIFT**
- Shift to more efficient, less carbon-intensive modes
  - Public transport, intercity and high-speed rail, and new mobility services (powered by renewable energy)
  - Zero emission logistics and last-mile delivery

**IMPROVE**
- Improve efficiency, vehicle technology and fuels
  - Fuel economy
  - Renewable fuels (e.g., sustainable biofuels, renewable electro-fuels)
  - Renewable-based electric vehicles

---

**Targets for Renewable Power and Electric Vehicles as of End-2020**

Note: Renewable power targets include only targets for a specific share of electricity generation by a future year. Where a jurisdiction has multiple targets, the highest target is shown. Nepal and Quebec show actual renewable power shares; both jurisdictions along with Iceland and Norway have already achieved nearly 100% renewable power. Electric vehicle targets vary; for details, see Reference Tables R6 and R8 in the GSR 2021 Data Pack.

Source: REN21 Policy Database.

---

Only 8 countries with targeted bans on internal combustion engine vehicles have 100% renewable power targets.
What is the story?

Renewables make their greatest contribution to the power sector. The share has risen quickly in recent years and reached 29% in 2020, up from 27% in 2018. The power sector continued to receive the bulk of renewable energy policy attention in 2020, as in previous years. Although feed-in policies remain a widely used mechanism, in 2020 the shift continued from feed-in policies to tenders and auctions.

In 2020, wind power and solar PV generated more than 20% of electricity in nine countries.
Global Investment in Renewable Power Capacity
Developed, Emerging and Developing Countries, 2010-2020

Note: Figure includes utility-scale renewable energy and small-scale solar projects and excludes large hydropower projects of more than 50 MW.
Source: BloombergNEF.

Solar PV mini-grids are increasingly the preferred technology for providing electricity access across Africa and Asia.

Renewable Energy Feed-in Tariffs and Tenders
2010-2020

Source: REN21 Policy Database.
Note: Figures include utility-scale renewable energy and small-scale solar projects and exclude large hydropower projects of more than 50 MW. The regions in this figure follow those presented in the BNEF Energy Transition Investment 2021 report and differ from the regional definitions included elsewhere in the GSR.

Source: BloombergNEF.
In 2020, solar power was the only renewable energy technology to experience an increase in investments.
More than 256 GW of renewable power capacity was added globally in 2020 – beating the previous record by nearly 30%.

¹ Per capita renewable power capacity (not including hydropower) ranking based on data gathered from various sources for more than 70 countries and on 2019 population data from the World Bank.

² Solar water heating collector ranking for total capacity is for year-end 2020 and is based on capacity of water (glazed and unglazed) collectors only. Data from International Energy Agency Solar Heating and Cooling Programme.

³ Not including heat pumps.

Note: Most rankings are based on absolute amounts of investment, power generation capacity or output, or biofuels production; if done on a basis of per capita, national GDP or other, the rankings would be different for many categories (as seen with per capita rankings for renewable power not including hydropower and solar water heating collector capacity).
What are the technology options?

Technologies that help increase the share of renewables in heating and cooling include solar thermal heating, geothermal heat, bioenergy and renewable electricity (e.g., heat pumps). Markets for solar thermal heating and heat pumps grew in 2020, and geothermal heat use is rising, while bioenergy use has been mainly flat in recent years.

Solar Water Heating Collectors Global Capacity
2010-2020

Gigawatts-thermal

501 Gigawatts-thermal
World Total

Note: Data are for glazed and unglazed solar water collectors and do not include concentrating, air or hybrid collectors. The drop in 2019 was caused by revised annual additions for China in 2019 and new assumptions for projecting total capacity in operation for 2019 and 2020.

Total average annual change:
- District heating: +1.2%
- Industry: +0.3%
- Buildings, modern bioenergy: +5.9%
- District heating, modern bioenergy: +1.4%

Source: Based on IEA.
What are the technology options?

Biofuels, including ethanol and biodiesel, make up most of the renewable energy contribution to the transport sector. Electric vehicles provide an opportunity to increase the renewable share with electricity. Biofuels production fell in 2020 in the wake of the COVID-19 crisis, but the overall share of biofuels in the sector remained stable.

On the contrary, sales of electric cars exploded, and some markets saw significant growth in the market share of electric cars.

The United States and Brazil, the two leading producers of biofuels, account for around 80% of global production.

Sales of electric cars grew 41% in 2020, while total car sales declined.
What are the technology options?

Installed renewable power capacity grew by more than 256 GW during the pandemic year 2020, the largest increase ever. Solar PV and wind power made up more than 90% of this increase and are the main drivers towards higher shares of renewables in the power sector. By the end of 2020, 34 countries had more than 10 GW of renewable power capacity in operation, up from 20 countries in 2010.

**Wind Power Capacity and Additions**

Top 10 Countries for Capacity Added, 2020

Continuing a trend going back to 2012, most of the newly installed power capacity in 2020 was renewable.

Note: Numbers above bars are gross additions, but bar heights reflect year-end totals. Germany’s net additions were slightly below those of Norway.
